Outline

Introduction

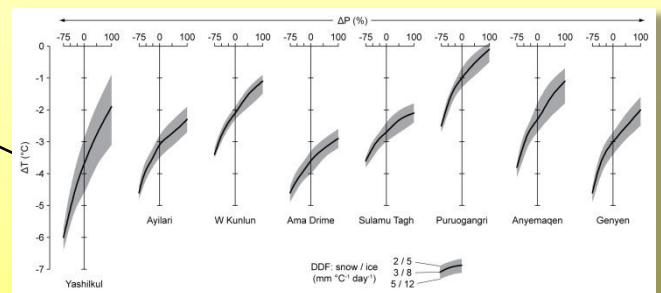

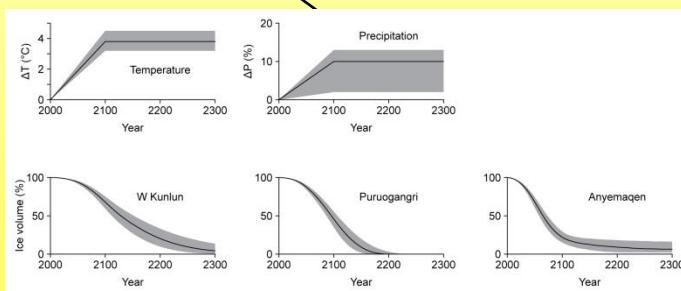

Methods

Glacial paleoclimate

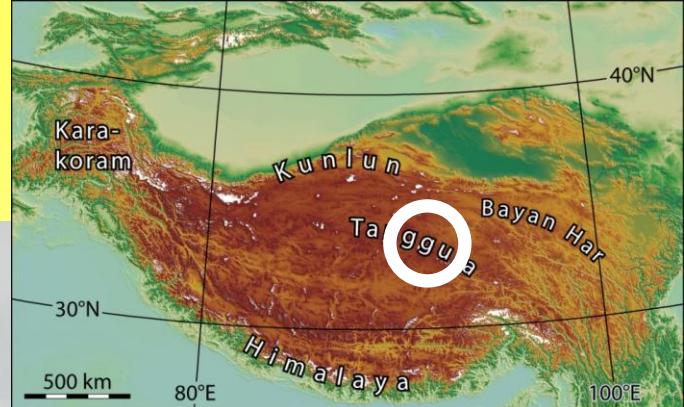

Projection

Conclusions

Limited glaciation of Tibet

Exposure age data: Schäfer et al. (2002)
Owen et al. (2005)
Colgan et al. (2006)

77 ka
71 ka
66 ka
62 ka
47 ka Distance to
43 ka glacier: 7.8 km

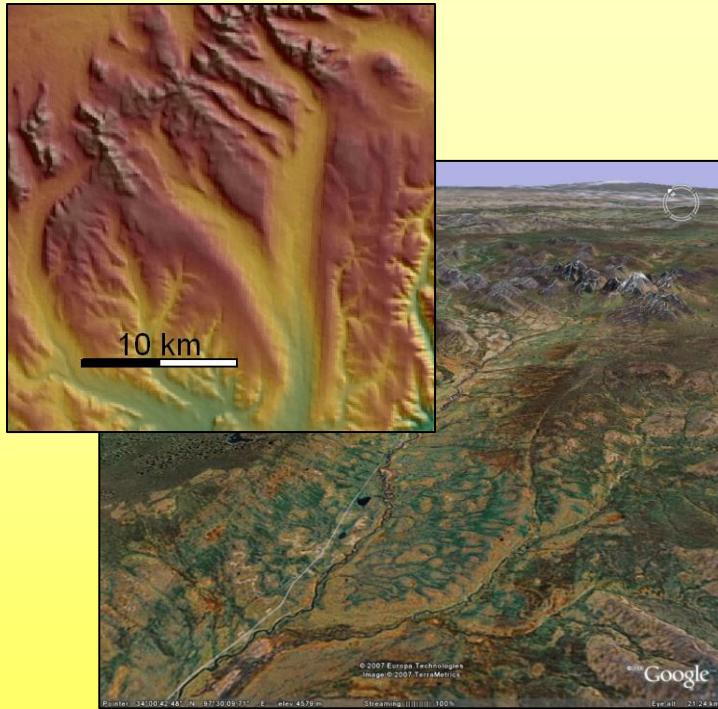

34 ka Distance to glacier: 3.1 km

Paleo-climate implications? Glacial geology + glacial modeling

Glacial landform mapping

Detailed mapping of glaciers, glacially eroded valleys, and moraines

- SRTM elevation model
- Landsat ETM+ images
- Google Earth

Glacier model

Higher order 3D ice flow model

Resolution: 250 m

Degree day mass balance model

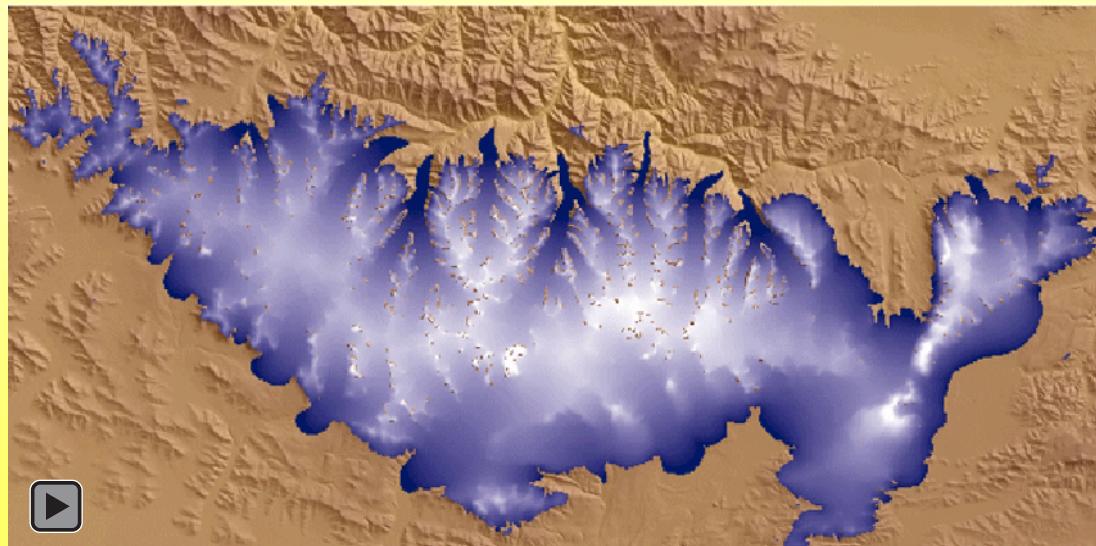

DDF_{snow} : 3 mm $^{\circ}\text{C}^{-1}$ day $^{-1}$

DDF_{ice} : 8 mm $^{\circ}\text{C}^{-1}$ day $^{-1}$

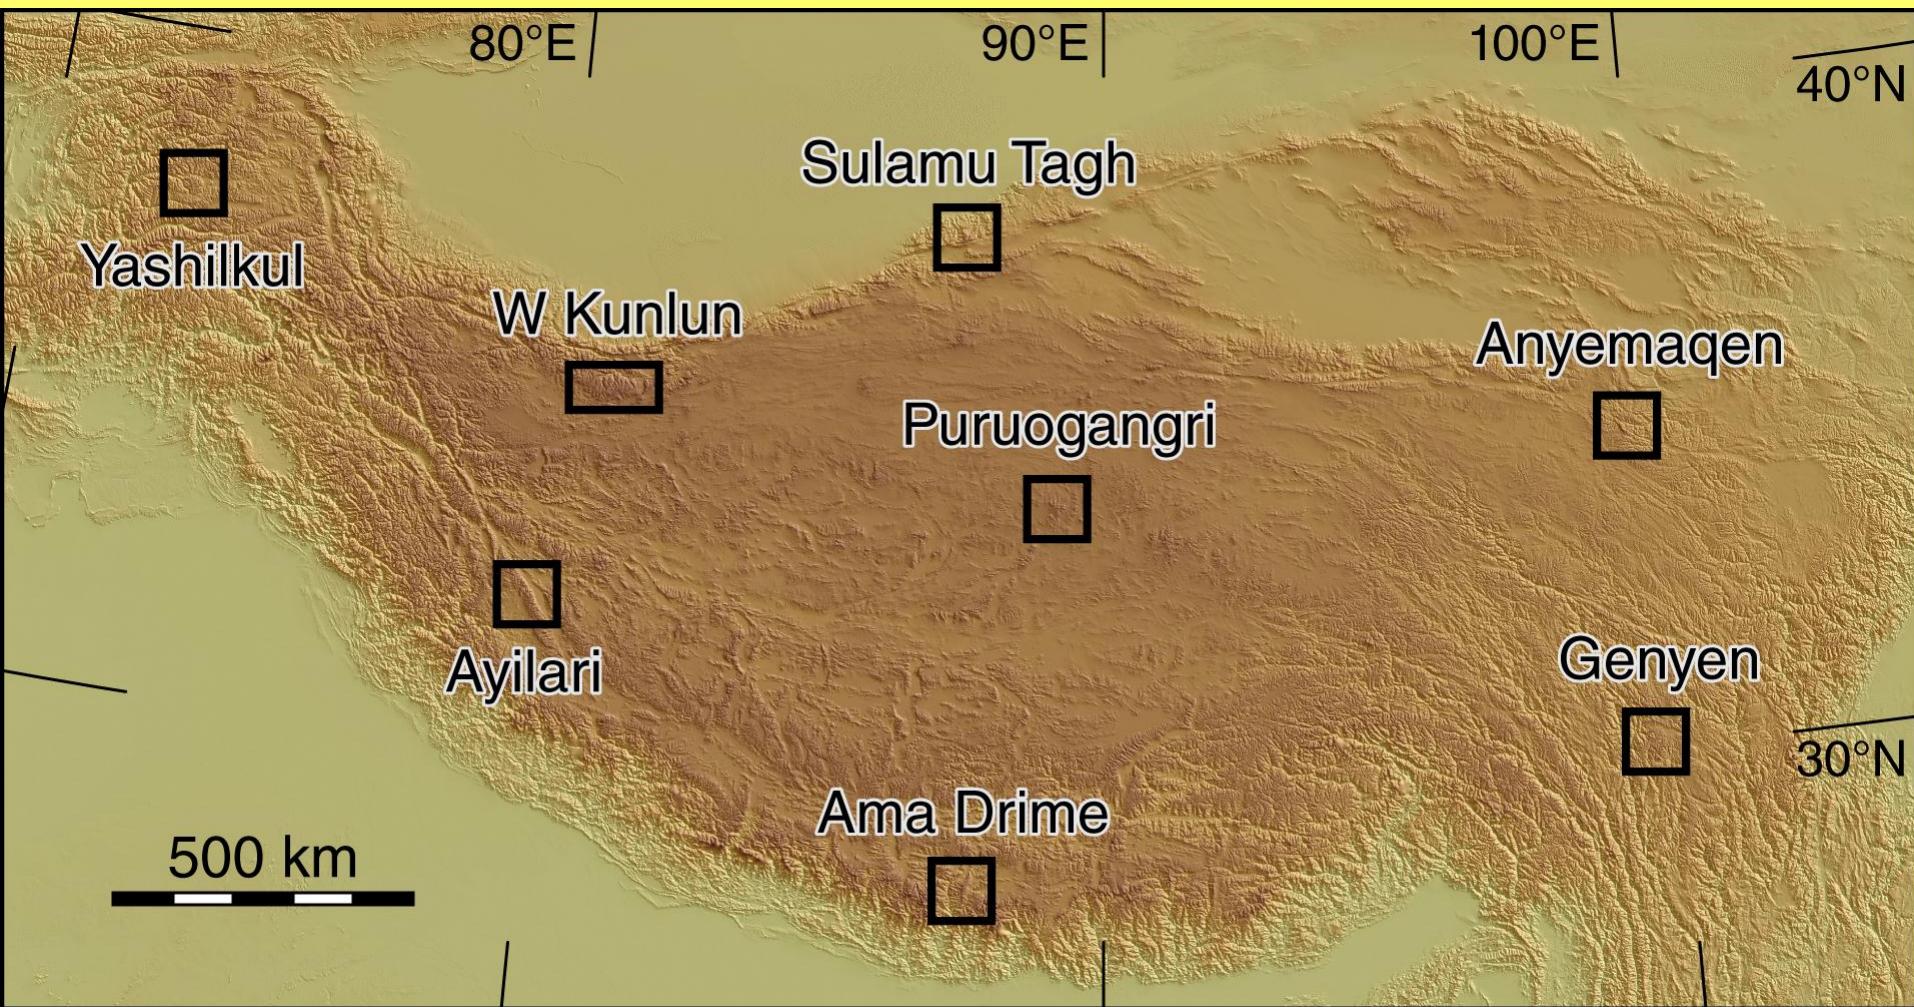

Input

SRTM topography

Mean monthly temperature and precipitation (WorldClim)

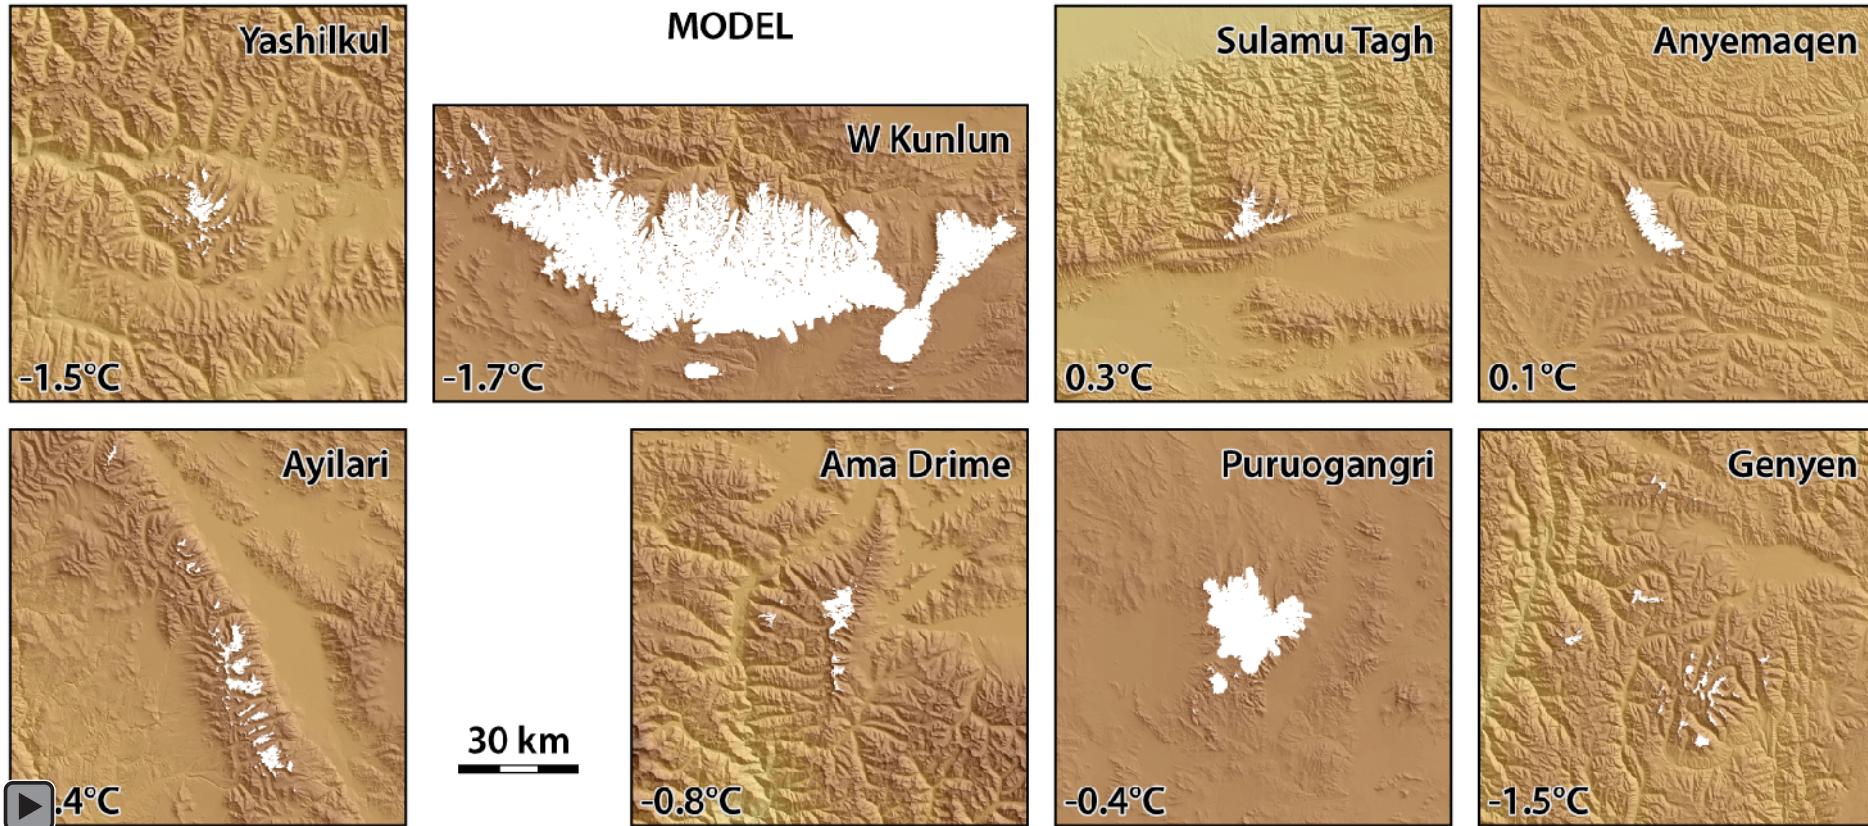

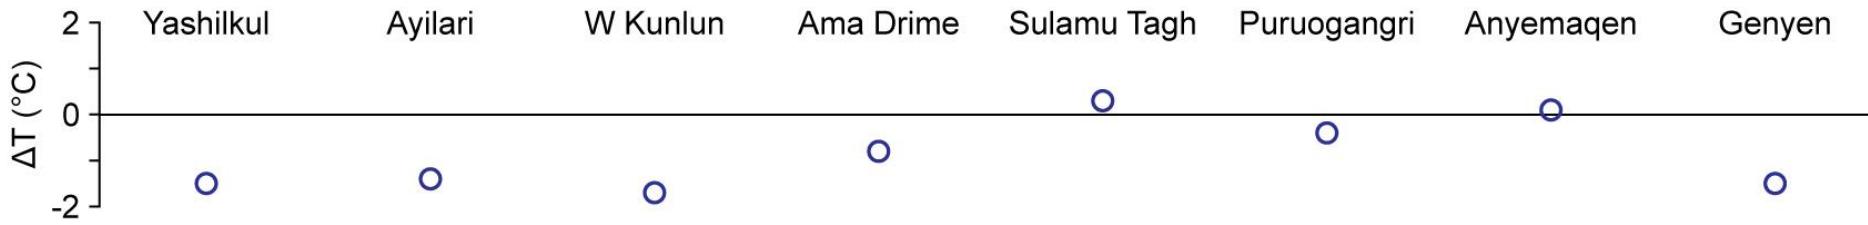

Glacier model domains

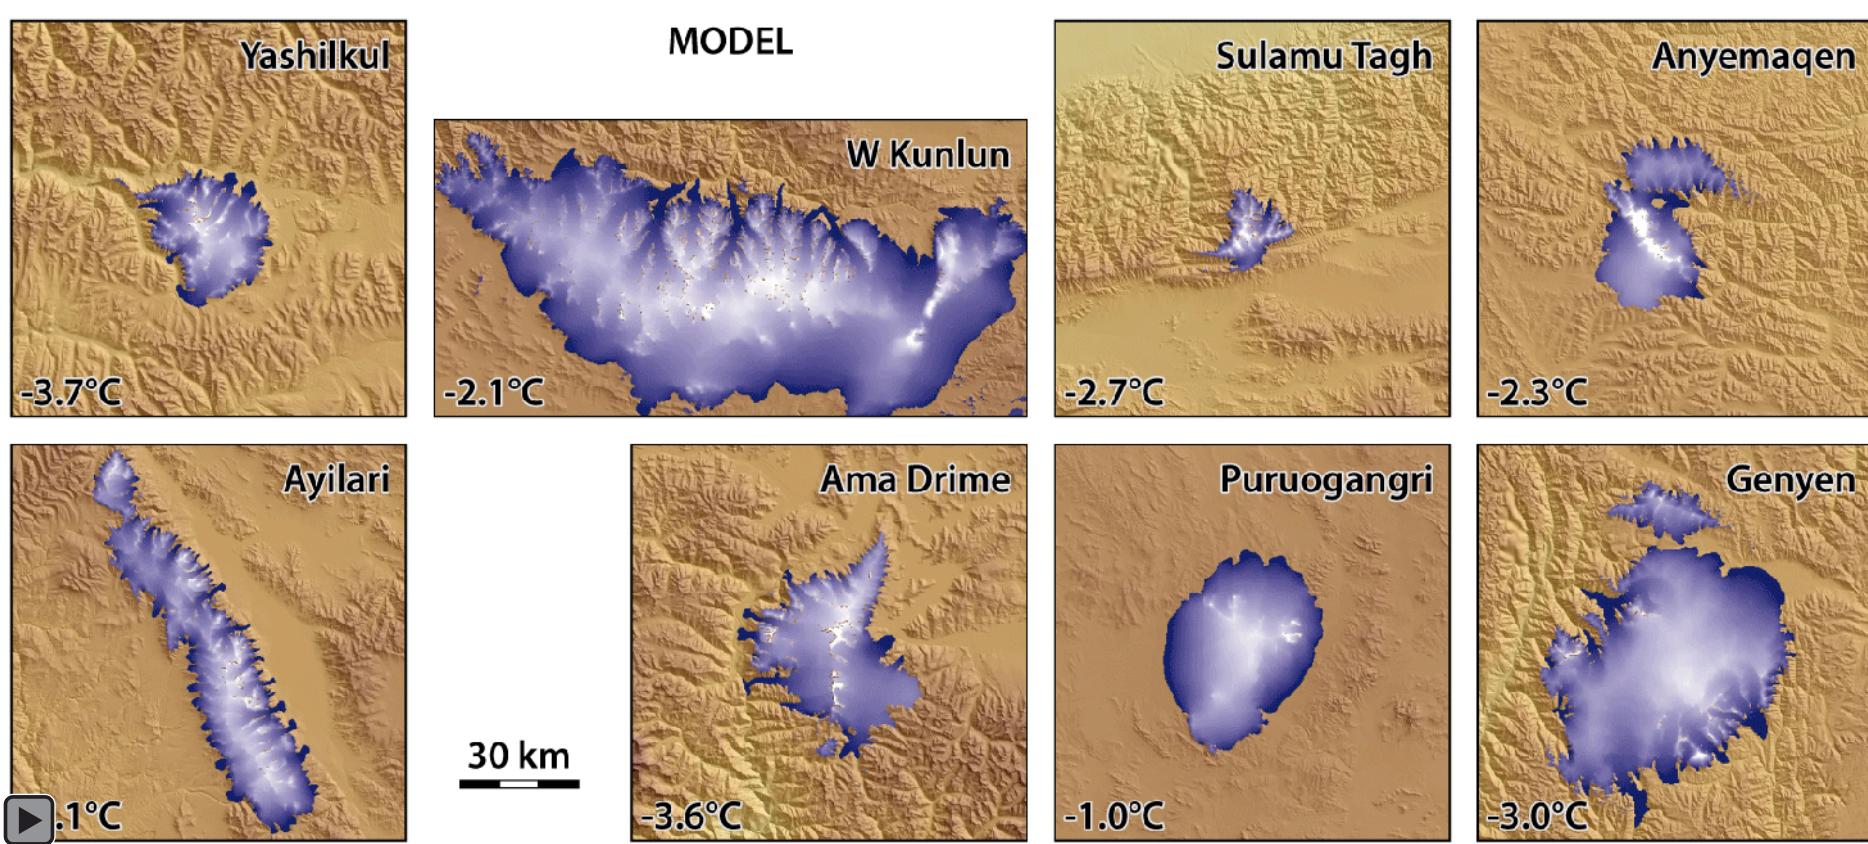

All model domains have present-day glaciers

For six domains there are cosmogenic exposure ages for past glaciations (>50 ka)

Temperature perturbations to reproduce present-day glaciers

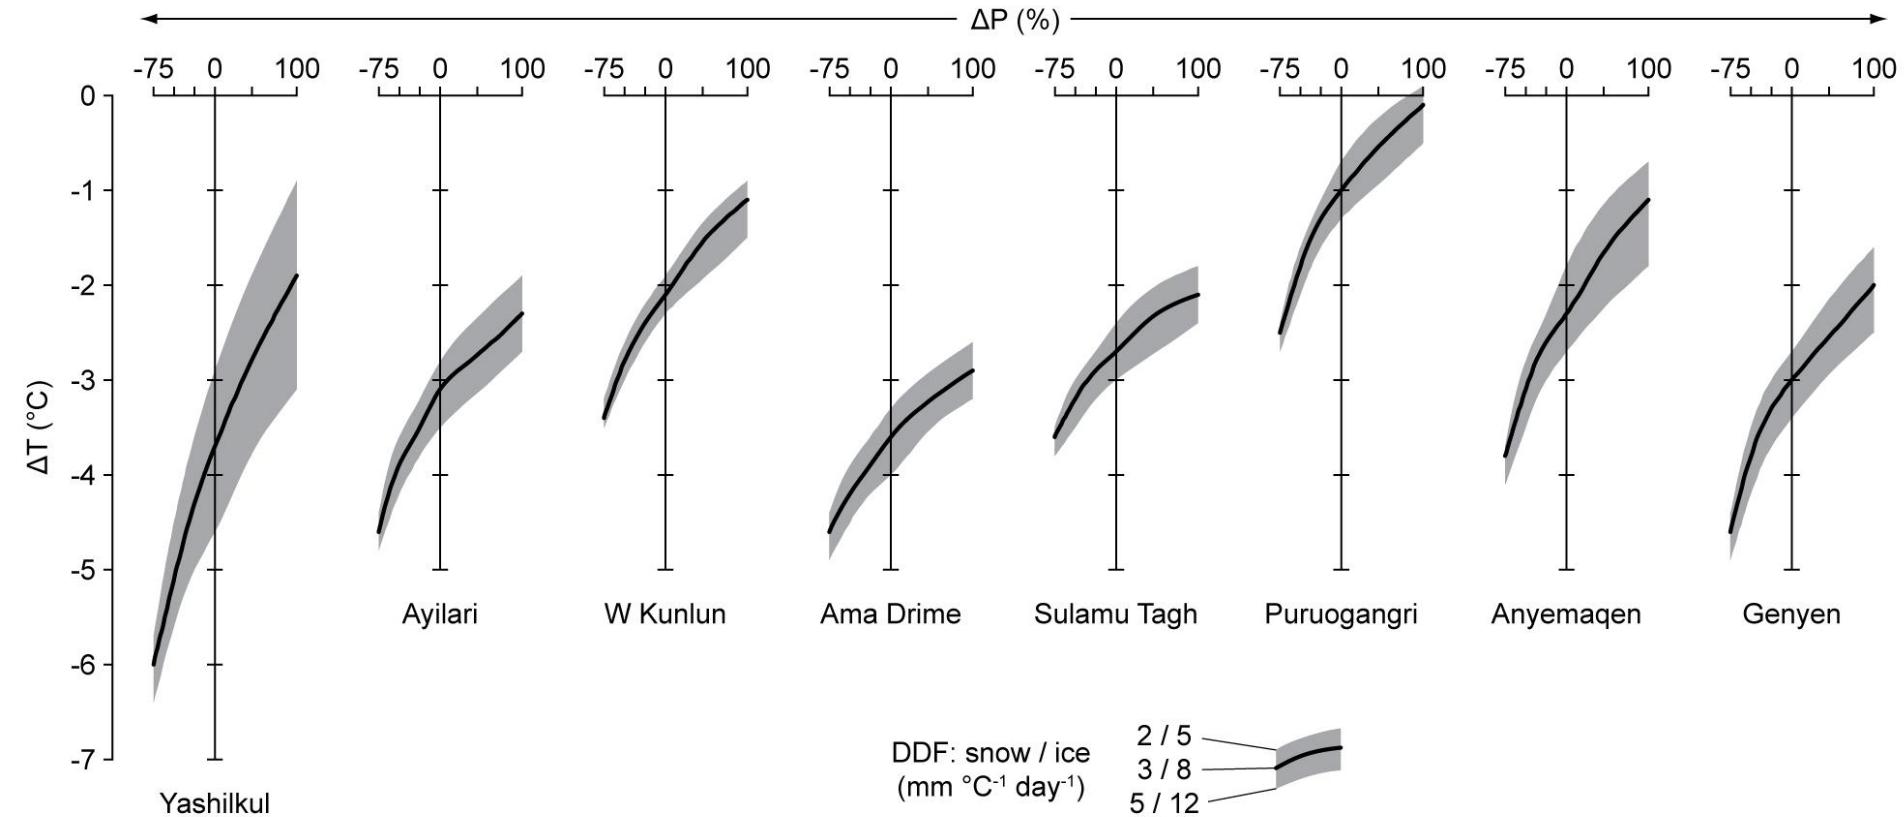

Climate perturbations for paleo-glaciation targets

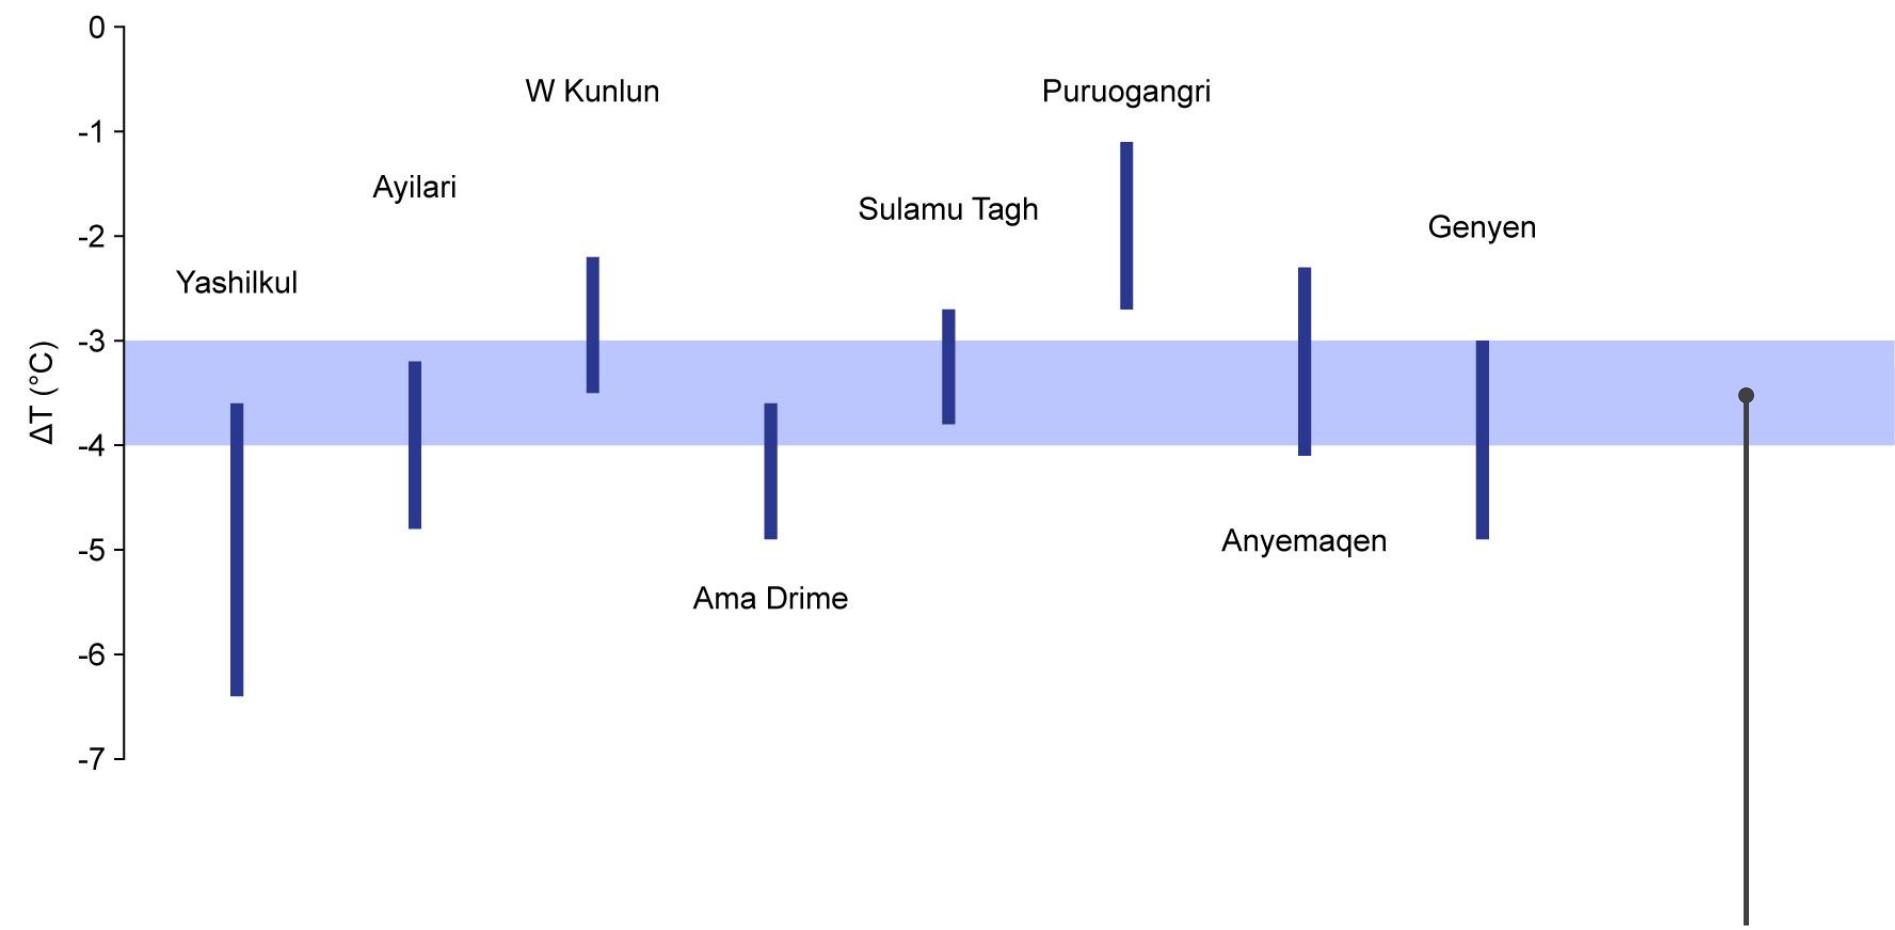

Modeling 5000 years forward with static temperature
and precipitation perturbations

Climate perturbations for paleo-glaciation targets

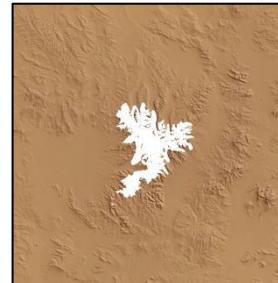

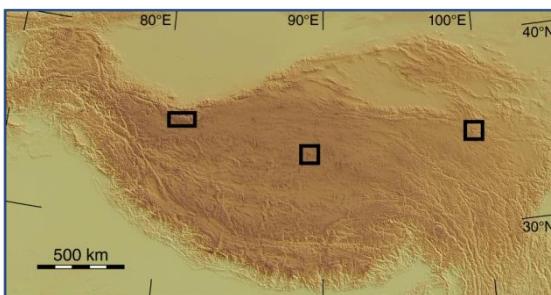

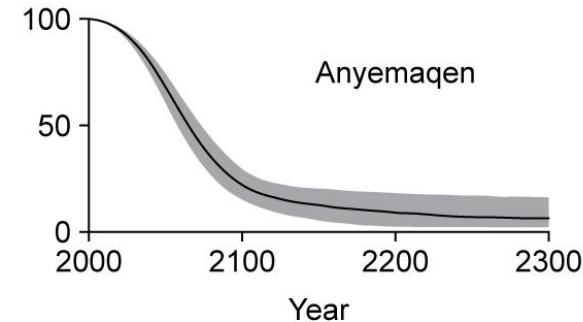

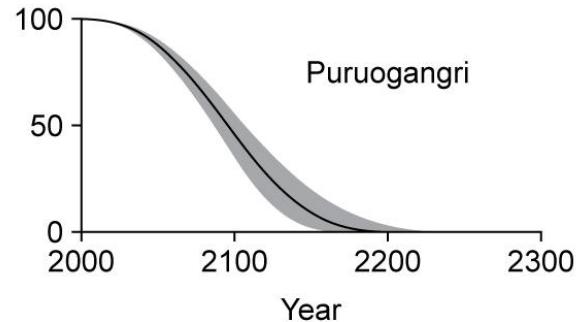

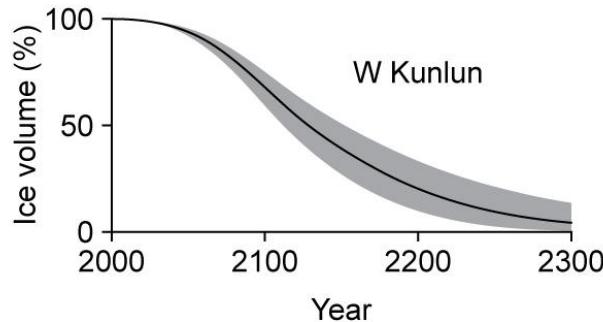

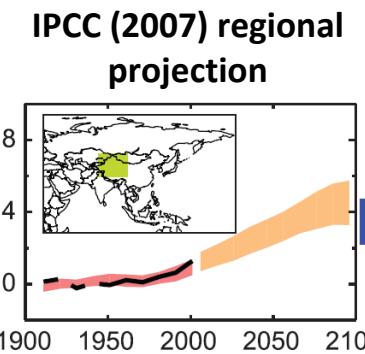

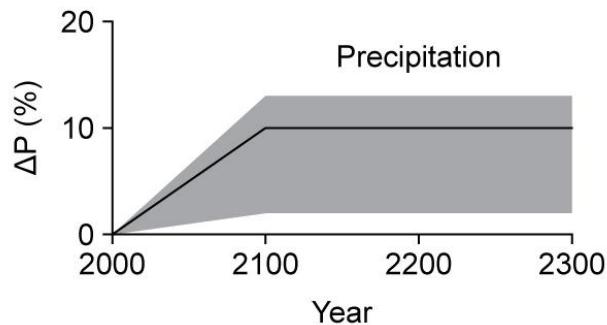

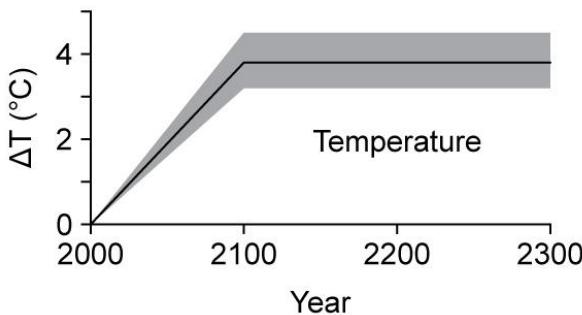

Assuming -25% to -75% ΔP

Max LGM summer cooling: 3-4°C
Schmidt et al. (2011): QSR
Miehe et al. (2011): QR

Glacier evolution with warming

Conclusions

- The Tibetan Plateau has experienced only limited cooling during the last few glaciations (max 2-6°C)
- Future warming of projected IPCC magnitude (3.2-4.5°C) would result in dramatic glacier loss

Thank you!
